

## AN431

# Temperature measurement and display using the MC68HC05B4 and the MC14489

By Jeff Wright,  
Motorola Ltd., East Kilbride

### INTRODUCTION

This application note is intended to show the basic building blocks of a temperature control system based on the MC68HC05Bx family of MCUs. Software routines in the application include look-up table interpolation, binary to BCD conversion, DegC to DegF conversion and the basis of a real time counter/clock. For temperature display the Multi-character LED display driver MC14489 is used, driven from the B4's SCI, resulting in simple hardware with a low component count. The temperature sensing element used here is a thermistor to allow easy interfacing to the A/D converter of the HC05B4, but the software principles shown would be the same for many other types of sensors. A software listing is included at the end of this application note.

### TEMPERATURE MEASUREMENT

A pre-calibrated thermistor was chosen as the temperature sensing element. Its characteristic curve over the temperature range of -40 to 80 °C is shown in Figure 1. To get the best accuracy from the HC05B4's on-board A/D, the input signal should be scaled to use as much of the available VRH-VRL range as possible. Here VRH is connected to Vdd and VRL is tied to Vss. In this case, using the thermistor as potential divider with a 20kΩ resistor results in a signal range of approximately 0.3V to 4.7V over the -40 to 80 °C temperature range. The voltage across the thermistor (input to the A/D), plotted against temperature, is shown in Figure 2.

Figure 1. Thermistor resistance vs Temperature

Figure 2. A/D input voltage vs Temperature (inset: circuit used)

As can be seen from Figure 2, the response is non-linear and so a look-up table approach is the simplest way of obtaining the required accuracy. The thermistor characteristics are stored as a series of points in a table in ROM and a linear interpolation between adjacent points is used to obtain the temperature that corresponds to a given A/D reading. The number of points that must be stored depends on how non-linear the response is and the required accuracy of the result. In this case 16 points were chosen; in order to keep the software simple (and

therefore fast), they are spread at intervals of 16 through the A/D result range of 0-255. For each point (16, 32, 48 etc.), the voltage on the A/D input was calculated and the corresponding temperature was obtained from the graph of Figure 2. These points were then used to form the look-up table shown in Figure 3, resulting in a temperature range of -40 to 79 °C. Figure 4 shows the reconstructed response of the thermistor obtained by linear interpolation of the points in the look-up table.

A/D RESULT	A/D (volts)	TEMP (°C)	TEMP (°C 2s Compl)
0	0	-	-
16	0.31	79	4F
32	0.63	56	38
48	0.94	43	2B
64	1.26	34	22
80	1.57	27	1B
96	1.88	21	15
112	2.20	15	0F
128	2.51	10	0A
144	2.82	5	05
160	3.14	-1	FF
176	3.45	-6	FA
192	3.77	-11	F5
208	4.08	-18	EE
224	4.39	-26	E6
240	4.71	-40	D8
255	5.0	-	-

Figure 3. Interpolated A/D input voltage vs Temperature

**Figure 4. Interpolated A/D input voltage vs Temperature**

The temperature reading is updated every second; the software to accomplish this is relatively simple:

The timer is set to overflow every 125 mS with a 4.1934 MHz crystal. The timer overflow interrupt routine updates the real time counters TICKS, SECS, MINS & HRS and sets the flag bit SEC every time a second has elapsed.

The main program loop is executed every second (via the SEC flag bit) and after checking the metric/imperial selector switch the temperature is measured by the subroutine ADCONV. This routine starts by reading the thermistor selector switch and setting up the A/D control register accordingly. An A/D conversion is then carried out four times on the selected channel and the results accumulated in the accumulator and the temporary register TEMP. This result is then divided by 4 by rotating, to obtain the average A/D result. The averaging technique is employed to try and reduce the effect of noise on the A/D input. The number of conversions to average is determined by time constraints and the noise levels in the surrounding environment. The upper nibble of the result is then used to access the look-up table to obtain the 'base' temperature value. If the temperature limit is exceeded then the TLIMIT flag is set before exiting from the routine.

Temperature table entries are stored in 2's complement form so that the interpolation between positive and negative values will work successfully. The interpolation is carried out by obtaining the difference between the base value and the next in the table, multiplying this by the lower nibble of the A/D result and then dividing by 16. This result is then subtracted from the base value to obtain the real temperature in 2's complement °C which is stored in the register NEWTMP before exiting from the routine. The difference information is subtracted from the base value rather than added because the thermistor has a negative temperature co-efficient (NTC) so that an increase in the A/D result corresponds to a drop in temperature.

If the imperial mode is selected (°F) then the next stage before updating the display is to convert from °C to °F and this is carried out in the subroutine CTOF.

Converting from °C to °F is accomplished by multiplying by 1.8 and adding 32. First the sign of the temperature in °C is stored via the flag bit NEGNUM, then the maximum °F limit (53 °C) is checked before the magnitude is multiplied by 1.8 (multiply by 115 and divide by 64). Again, use is made of rotating to do the dividing, in order to increase execution speed. The sign of the result is then restored and 32 added to obtain the temperature in 2's complement °F.

## TEMPERATURE DISPLAY

An MC14489 multi-character display driver was chosen for this purpose as it can be easily interfaced to a wide range of Motorola MCUs, requires almost no external components and has a character set that includes the degree symbol (°). The MC14489 can also be cascaded if the application was expanded to require a larger display. The MC14489 would normally be driven from an SPI on the MCU but here, since the 68HC05B family does not have an SPI, use is made of the SCI clock output feature that is available on this family.

Before the temperature can be written to the display driver it has to be converted into the correct data format.

The first stage of this is to convert from 2's complement binary to BCD. This is carried out in the routine CONBCD which is called from SETDISP. The sign of the temperature is stored in the flag bit NEGNUM before SETDISP is called; then, after first checking if the TLIMIT flag is set, the temperature is converted to BCD in DEC0-2 by CONBCD. This is accomplished by rotating left the binary number followed immediately by a rotate left of the BCD result; this has the effect of multiplying the current BCD result by 2 and adding in the new binary bit at the same time. After each rotate the BCD registers are checked and adjusted for overflow (>\$09) before the bit counter contained in the index register is decremented. This process of rotate then adjust is continued until all the binary bits have been used; the BCD result will then be resident in the registers DEC0, 1 & 2.

The rest of the routine SETDISP is concerned with setting up the display registers DISP1, 2, 3 and the display control register DISPC. The MC14489 data format is msb first whereas the 68HC05B4 SCI transmits lsb first; this means that the bit order of the data stream has to be stored in reverse in the display registers. This can be confusing when trying to work out the codes that have to be stored in the B4 to generate a specific character.

Figures 5a and 5b show the 14489 data format and the corresponding bit positions in the B4 registers DISP1, 2, 3 & C. The sign of the temperature is restored and the numeric display registers are configured to display '-' if the temperature limit has been exceeded before exiting from the SETDISP routine.

The main program loop then calls the subroutine DISPL which actually transmits the contents of the display registers to the MC14489 via the SCI. The MC14489 contains special Bit Grabber circuitry that allows either the internal display registers or the configuration register to be updated without address or steering bits so that updating the display involves a simple transmission of either 3 bytes for the display registers or 1 byte for the configuration register. Even for cascaded 14489s there is no need for address bits – see the MC14489 data sheet for more details.

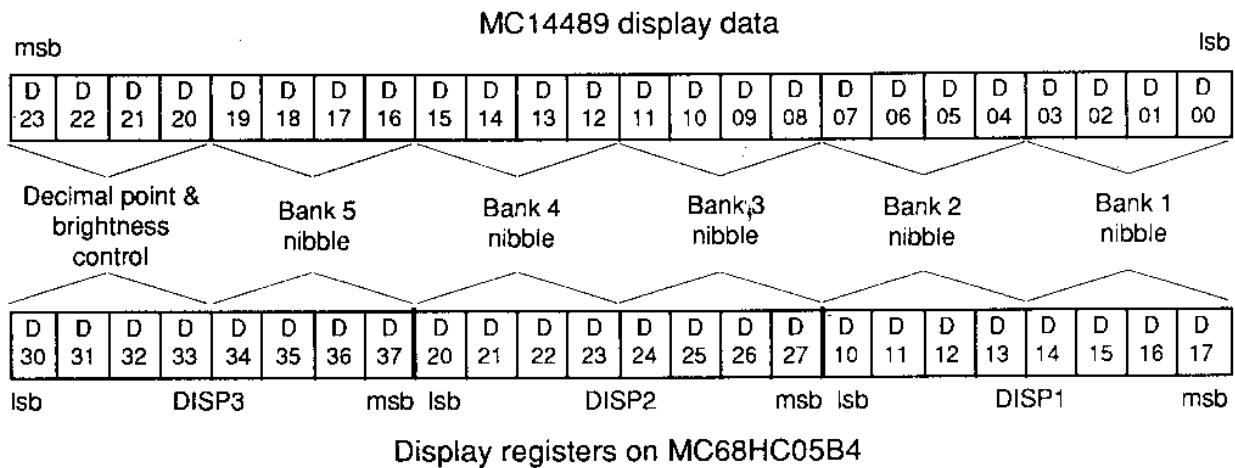

The MC14489 can be clocked at up to 4 MHz at 5 volts so here the maximum transmit baud rate of the SCI is used – 131.072 KHz with a 4.19304 MHz crystal. The transmission of the display data only takes place if there has been a change in the data since the last time. If there has been a change, the 3 data registers are transmitted in turn starting with DISP3 and the OLD registers are updated ready for the change check next time round. After the last byte has gone, the SCI and 14489 are disabled before returning to the main loop.

The last subroutine called from the main program is the 14489 configuration update routine DISCON. This routine operates in a similar manner to DISPL, checking to see if there has been a change to the config. data before transmitting it.

This completes the operation of the program which now jumps back to the start of the main loop and waits for the SEC bit to be set again before repeating the temperature measurement and display sequence.

**Figure 5a. MC14489 to MC68HC05B4 display register mapping**

**Figure 5b. MC14489 to MC68HC05B4 display register mapping**

### HARDWARE

As already mentioned, the use of the MC14489 results in a very low component count for the application; the hardware schematic can be seen in Figure 6. The only I/O pins required are for reading the option switches and for controlling the enable of the MC14489. Pull-downs are required on the clock and data pins as these become high impedance when the SCI is disabled. The LED displays are common cathode; a single external resistor is all that is required to set the brightness

level of the displays. In this case though, a light dependent resistor, R12 (ORP12), has been used to control the display brightness for a variety of background lighting conditions. The resistance of R12 decreases with increasing light and so R11 must be incorporated to ensure that the maximum source current spec. of the MC14489 is not exceeded in very bright lighting conditions. R13 ensures there is still enough drive current for the LEDs in dark conditions.

### APPLICATION AREAS

As mentioned in the introduction, this application note is designed only to show some fundamental building blocks of a temperature control system based on the 68HC05Bx family of MCUs. Where possible, the software has been written in a modular fashion, so that the routines can easily be transported to another application and the binary to BCD routine could be expanded to handle larger numbers. The large number of I/O,

PWMs and timer functions unused show that the 68HC05B family has plenty of functionality left to perform other control functions. For example, in process control, fluid flow or speed sensors could be connected to the timer input capture pins, pressure sensors to the other A/D pins, a keypad to the I/O lines and the other I/O & PWMs used to perform output control functions.
